Abstract: Brain tumor detection using MRI image calculation accurate value. Another process is CT- scan; X-ray not correctly identified precise size and arie in this two method. In using Image processing and Matlab –SFCM algorithm calculate particular size and accurate arie value without losing information and correct. In particular fined three stages in patients first one Normal, Second one – Begin, Third one- Malignant. Brain tissue is susceptible but manually method using not possible accurate size and size. These project in PNN (Probabilistic Neural Network) classified patients is Normal, Begin, Malignant and SFCM – the Spatial Fuzzy C-Mean algorithm using calculate Sensitivity, specificity, accuracy overall process in less time.PNN method gives input to MRI Image, this image compeer to the database of MRI image then classification is done.After identification process full this database store in raspberry –pi kit only put image file name particular in program witch image result send to doctor mail id. Raspberry- Pi kit transmitting the image by mail to specific doctor mail- ID in less time without opening mail identifier of the user.

Keywords—MR images, tumor detection method, Fuzzy C -Means Clustering , medical imaging system. Raspberry –Pi hardware.

I INTRODUCTION

In this tumor is defined as the irregular growth of the tissues.

The brain tumor is an abnormal mass of tissue in which cells grow up and multiply uncontrollably. Brain tumors may be Normal or begin, and either malignant. A metastatic brain tumor stage is cancer which has spread from anywhere in the body to the brain. MRI brain tumor segmentation provides useful information for surgical planning and medical diagnosis.

Types of Tumor
There are three general types of Tumor:

1. Normal
2. Begin
3. Malignant

1. Normal Tumor:- This particular type doesn’t affect neighboring healthy tissues and also does not expand to non-adjacent.

2. Benign Tumor:- In this types a precancerous stage. It means considered as a condition, if not accurately treated it may lead to cancer.

3. Malignant Tumor:- In this types which grow worst with the passage of time and ultimately results in the death of a person. The term malignant tumor is typically utilized for the description of cancer.

In this process, real-time diagnosis of tumors using more reliable algorithms and the primary focus of the latest developments in medical image and detection of a brain tumor in MRI images and CT scan images the process is an active research area.MRI image is used detect the biomedical structure of the body. This technique use detects the difference in the tissues better than to CT scan. MRI technique as very important for the brain tumor detection MRI uses the strong magnetic field to follow the nuclear magnetization then radio frequencies change the arrangement of the magnetization which can be identified by the scanner. That signal can be further processed to build the more information of the body. MRI image is safe as compared to CT scan image as it does not affect the human body. In this process MRI image not find an accurate value of brain tumor. The manual calculates not accessible by using MRI image. Because of MRI HD-Image is burred and not calculate the precise amount. But MRI –image used in PNN
(Probability Neural Network) to identify to patient witch stage (Normal, Begin, Malignant) and patient detect brain tumor the output of PNN give to simple fuzzy C-mean (SFCM) algorithm or don’t identify brain tumor stop process. SFCM algorithm most using calculate tumor size in percentage (%). This algorithm identified in less time accurate value estimates. The computed value or all information to patient give to the doctor by using Raspberry – Pi. This data transfer to doctor mail id or patient mail id without losing any information. Raspberry-pi kit is easy to interface with computer and laptop, and inbuilt RAM, WIFI – Director, less power consumption, accuracy is more than another processor.

II PROPOSED METHOD

Pre-processing:-

The bias field distortion alters MRI images. The makes the intensity of the same masses to vary over that picture.

However, this is not enough to ensure that the intensity distribution of a tissue type is in a similar intensity scale across different subjects for the same MRI sequence, which is an explicit or implicit assuming in most segmentation techniques. In fact, it can vary equally if the image of the same patient lives taken in the same scanner in different time points, or in the presence of pathology. So, to make the contrast and intensity range more similar across patients and acquisitions, we apply the intensity normalization method proposed by Nyul’ et al. on each sequence. In this intensity normalization method, a set of intensity landmarks \( IL = fpc1; ip10 ; ip20 ; \ldots ; ip90 ; pc2g \) are learned for each sequence from the training set. \( pc1 \) and \( pc2 \) are chosen for each MRI sequence as described. April represents the intensity at the \( n \)th percentile. After training, the intensity normalization is accomplished by linearly transforming the original intensities between two landmarks into the corresponding learned landmarks. In this way, the histogram of each sequence is more similar across subjects. After normalizing the MRI images, we compute the mean intensity value and standard deviation across all training patches extracted for each sequence. Then, we normalize the patches on each sequence to have zero mean and unit variance1. The mean and standard deviation computed in the training patches are used to normalize the testing patches.

DWT-Transforms: Image fusion ends up very famous for its application in various real lifestyles applications such as remote sensing packages, clinical image analysis. The non-idle nature of sensible imaging structures the capture pics is corrupted by noise. Consequently, Fusion of pics is an included technique in which the reduction of noise is essential. Discrete Wavelet rework (DWT) has an extensive range of application in the noise photographs. But shift-invariance is vital in making sure strong sub-band fusion. To conquer this, dual-tree complex Wavelet remodels (DT-CWT) is delivered for fusion of noise pictures. Complicated wavelet rework is complicated valued extension of the usual wavelet. Experiments are finished on some of the photographs like SAR pics, MRI photographs, doll photos and toy images to evaluate the performance of the proposed technique. Effects show that the DT-CWT technique is higher than that of DWT technique in phrases of first-class measures peak signal-to-noise ratio, pass correlation and image visual great.

Gray-Level Co-Occurrence Matrix

This process using creates a GLCM, use the gray co-matrix function. Particular function form gray level Co-occurrence matrix GLCM by calculation how often a specific pixel with the intensity value I occur in a specific spatial relationship to a pixel with the value j. This process number of gray levels in the image determines the size of the GLCM. By default, gray co-matrix uses scaling to reduce the number of intensity values in an image to eight, and you can use the Num Levels and the Gray Limits parameters to control this scaling of gray levels. In GLCM has revealed specific properties about the spatial distribution of the gray levels in the texture image.

For example, the GLCM is directed along the diagonal and texture is coarse concerning the specified offset .in GLCM can also derive stoical measures, and the derive
statistics from GLCM and more information from plot correlation show in the following fig. how to gray co-matrix calculate the 1st three value in given GLCM.

**Probabilistic Neural Network**

In this process of probabilistic neural networks is used in for classification problems. PNN input is present, the first layer computes distances from the input vector to the training input vectors and produces a vector whose elements indicate how close the information is to a training input. It is second stage sum of the calibration for each class input to produces net output a particular vector of probabilities. The final stage to compute transfer function given out stage. In second stage pick going maximum prospects. His delivers one for class and zero used other courses. Show below process architecture system.

**Fuzzy C-mean clustering:-**

C- mean Clusters are identified via similarity measures. In this similarity tests using rules include distance, connectivity & intensity. Finding different similarity to based on data or app simple fuzzy c-means algorithm his very similar to K –means algorithm. A fuzzy cluster is all point degree of belonging to a group in the fuzzy logic or his related entirely just one cluster. This point edge of the bunch is to the lesser degree to the points in the center of the group. Overview of comparison of the different fuzzy clustering algorithm is available.

**Fuzzy c-means clustering**

The FCM algorithm is several generally used fuzzy clustering algorithms. The FCM algorithm attempts to partition a finite collection of elements X={,.....} into a collection of c fuzzy clusters concerning some given criterion. The algorithm means based on minimization from the resulting objective function:

\[
J_m = \sum_{i=1}^{N} \sum_{j=1}^{C} u_{ij}^m \| x_i - C_j \|^2
\]

Where m (the Fuzziness Exponent) is one exact number greater than 1. N is the amount of data, C is the number of groups. uij is the degree of a group of xi in the cluster j. xi is the Ith of d-dimensional measured data, Cj is the d dimension middle of the cluster, and \(\|\cdot\|\) is any norm expressing the relation between any measured data and the middle. \(\varepsilon\)

- Summation of membership of each data point should be equal to one.

**III RASPBERRY- PI SYSTEM**

This model is an essential part of communication between the computer to Human, less time to transmitted information regarding brain tumor give to doctor mail id. Without losing information , this model using less power apply and inbuilt WI-FI model to communicate to brain detection H/W to Computer .Above given basic diagram model for raspberry - pi.

**IV RESULT**

The following are the instances of the proposed methods result. It is a step by step projection of the proposed methods.
Figure 1. Show the give the input of MRI image to Matlab processing. Figure 2. preprocessing removing noise throw the image. show in Figure 3. convert of using DWT transfer method and GLCM method particular image. Figure 4. Compare Input MRI image with the database using Probabilistic Neural Network (PNN) and classification specific patient Normal, Begin, Malignant in Figure 5. Segmentation process to the identified aria of tumor shown in Figure 6. Overall process accuracy, specificity, and sensitivity finding shown in Figure 7. Raspberry-pi kit using send data to doctor mail-Id show result in Figure 8. Efficiency is more in less time without losing information.

V. ADVANTAGES

- It can segment the Brain regions from the image accurately.
- Classifying the Brain Tumor images for accurate detection is used.
- Brain Tumor will be seen at an early stages
- These techniques allow us to identify even the smallest abnormalities in the human body.
- The various types of medical imaging processes available to us, MRI is the most reliable and safe

VI. DISADVANTAGES

- Over all process more Initial cost more.

VII. APPLICATION

- Brain Tumor diagnosis system for medical application

VIII. CONCLUSION

Here an automated brain detection method using PNN and Spatial Fuzzy algorithm is proposed in this work. The experimental results regarding qualitative and quantitative metrics of the proposed algorithm and another state of art technique are prepared with better performance of a proposed neural network is demonstrated.

In our future work, we are doing it to implement in the FPGA board for the efficient use of them in the proposed architecture.
